University of New South Wales

TOPIC 3: THE FAST FOURIER TRANSFORM

# Coefficient vs value representation of polynomials

- Every polynomial  $P_A(x)$  of degree  $n$  is uniquely determined by its values at any  $n + 1$  distinct input values  $x_0, x_1, \dots, x_n$ :

$$P_A(x) \leftrightarrow \{(x_0, P_A(x_0)), (x_1, P_A(x_1)), \dots, (x_n, P_A(x_n))\}$$

- If  $P_A(x) = A_n x^n + A_{n-1} x^{n-1} + \dots + A_0$ , we can write in matrix form:

$$\begin{pmatrix} 1 & x_0 & x_0^2 & \dots & x_0^n \\ 1 & x_1 & x_1^2 & \dots & x_1^n \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & x_n & x_n^2 & \dots & x_n^n \end{pmatrix} \begin{pmatrix} A_0 \\ A_1 \\ \vdots \\ A_n \end{pmatrix} = \begin{pmatrix} P_A(x_0) \\ P_A(x_1) \\ \vdots \\ P_A(x_n) \end{pmatrix}. \quad (1)$$

- It can be shown that if  $x_i$  are all distinct, then this matrix is invertible.

# Coefficient vs value representation of polynomials - ctd.

- Thus, if all  $x_i$  are distinct, given any values  $P_A(x_0), P_A(x_1), \dots, P_A(x_n)$  the coefficients  $A_0, A_1, \dots, A_n$  are uniquely determined:

$$\begin{pmatrix} A_0 \\ A_1 \\ \vdots \\ A_n \end{pmatrix} = \begin{pmatrix} 1 & x_0 & x_0^2 & \dots & x_0^n \\ 1 & x_1 & x_1^2 & \dots & x_1^n \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x_n & x_n^2 & \dots & x_n^n \end{pmatrix}^{-1} \begin{pmatrix} P_A(x_0) \\ P_A(x_1) \\ \vdots \\ P_A(x_n) \end{pmatrix} \quad (2)$$

- Equations (1) and (2) show how we can commute between:
  - a representation of a polynomial  $P_A(x)$  via its coefficients  $A_n, A_{n-1}, \dots, A_0$ , i.e.  $P_A(x) = A_n x^n + \dots + A_1 x + A_0$
  - a representation of a polynomial  $P_A(x)$  via its values

$$P_A(x) \leftrightarrow \{(x_0, P_A(x_0)), (x_1, P_A(x_1)), \dots, (x_n, P_A(x_n))\}$$

# Our strategy to multiply polynomials fast:

- Given two polynomials of degree at most  $n$ ,

$$P_A(x) = A_n x^n + \dots + A_0; \quad P_B(x) = B_n x^n + \dots + B_0$$

- convert them into value representation at  $2n + 1$  distinct points  $x_0, x_1, \dots, x_{2n}$ :

$$P_A(x) \leftrightarrow \{(x_0, P_A(x_0)), (x_1, P_A(x_1)), \dots, (x_{2n}, P_A(x_{2n}))\}$$
$$P_B(x) \leftrightarrow \{(x_0, P_B(x_0)), (x_1, P_B(x_1)), \dots, (x_{2n}, P_B(x_{2n}))\}$$

- multiply them point by point using  $2n + 1$  multiplications:

$$\left\{ (x_0, \underbrace{P_A(x_0)P_B(x_0)}_{P_C(x_0)}), (x_1, \underbrace{P_A(x_1)P_B(x_1)}_{P_C(x_1)}), \dots, (x_{2n}, \underbrace{P_A(x_{2n})P_B(x_{2n})}_{P_C(x_{2n})}) \right\}$$

- Convert such value representation of  $P_C(x)$  to its coefficient form

$$P_C(x) = C_{2n}x^{2n} + C_{2n-1}x^{2n-1} + \dots + C_1x + C_0;$$

- Key Question:** What values should we take for  $x_0, \dots, x_{2n}$  to avoid “explosion” of size when we evaluate  $x_i^n$  while computing  $P_A(x_i) = A_n x_i^n + \dots + A_0$ ?

# Complex numbers revisited

Complex numbers  $z = a + ib$  can be represented using their *modulus*  $|z| = \sqrt{a^2 + b^2}$  and their *argument*,  $\arg(z)$ , which is an angle taking values in  $(-\pi, \pi]$  and satisfying:

$$z = |z|e^{i \arg(z)} = |z|(\cos \arg(z) + i \sin \arg(z)),$$

see figure below.

# Complex numbers revisited

Recall that

$$z^n = \left(|z|e^{i \arg(z)}\right)^n = |z|^n e^{i n \arg(z)} = |z|^n (\cos(n \arg(z)) + i \sin(n \arg(z))),$$

see the figure.

# Complex roots of unity

- *Roots of unity of order  $n$*  are complex numbers which satisfy  $z^n = 1$ .
- If  $z^n = |z|^n (\cos(n \arg(z)) + i \sin(n \arg(z))) = 1$  then  $|z| = 1$  and  $n \arg(z)$  is a multiple of  $2\pi$ ;
- Thus,  $n \arg(z) = 2\pi k$ , i.e.,  $\arg(z) = \frac{2\pi k}{n}$
- We denote  $\omega_n = e^{i 2\pi/n}$ ; such  $\omega_n$  is called a *primitive root of unity of order  $n$* .

Roots of unity of order 16

- A root of unity  $\omega$  of order  $n$  is *primitive* if all other roots of unity of the same order can be obtained as its powers  $\omega^k$ .

# Complex roots of unity

- For  $\omega_n = e^{i 2\pi/n}$

$$((\omega_n)^k)^n = (\omega_n)^{n k} = ((\omega_n)^n)^k = 1^k = 1$$

Thus,  $\omega_n^k = (\omega_n)^k$  is also a root of unity, and it can be shown that it is primitive just in case  $k$  is relatively prime with  $n$ .

- Since  $\omega_n^k$  are roots of unity for  $k = 0, 1, \dots, n-1$  and there are exactly  $n$  roots of unity of order  $n$  (i.e., solutions to the equation  $x^n - 1 = 0$ ) we get that every root of unity of order  $n$  is of the form  $\omega_n^k$ .
- For a product of any two roots of unity  $\omega_n^k$  and  $\omega_n^m$  of the same order we have  $\omega_n^k \omega_n^m = \omega_n^{k+m} = \omega_n^l$  where  $0 \leq l < n$  and  $l = (k+m) \bmod n$ .
- Thus, product of any two roots of unity of the same order is just another root of unity of the same order.
- So in the set of all roots of unity of order  $n$ , i.e.,  $\{1, \omega_n, \omega_n^2, \dots, \omega_n^{n-1}\}$  we can multiply any two elements or raise an element to any power without going out of this set.
- Note that this is not true for addition, i.e., the sum of two roots of unity is NOT another root of unity!

# Complex roots of unity

- **Cancellation Lemma:**  $\omega_{kn}^{km} = \omega_n^m$ .

Proof:

$$\omega_{kn}^{km} = (\omega_{kn})^{km} = (e^{i\frac{2\pi}{kn}})^{km} = e^{i\frac{2\pi km}{kn}} = e^{i\frac{2\pi m}{n}} = (e^{i\frac{2\pi}{n}})^m = \omega_n^m$$

- Thus, in particular,  $(\omega_{2n}^k)^2 = (\omega_{2n}^2)^k = \omega_{2n}^{2k} = \omega_n^k$ ;
- So squares of the roots of unity of order  $2n$  are just the roots of unity of order  $n$ .

# The Discrete Fourier Transform

- Let  $A = \langle A_0, A_1, \dots, A_{n-1} \rangle$  be a sequence of  $n$  real or complex numbers.
- We can form the corresponding polynomial  $P_A(x) = \sum_{j=0}^{n-1} A_j x^j$ ,
- We evaluate it at all complex roots of unity of order  $n$ , i.e., we compute  $P_A(\omega_n^k)$  for all  $0 \leq k \leq n-1$ .
- The sequence of values  $\langle P_A(1), P_A(\omega_n), P_A(\omega_n^2), \dots, P_A(\omega_n^{n-1}) \rangle$ , is called **the Discrete Fourier Transform (DFT)** of the sequence  $A = \langle A_0, A_1, \dots, A_{n-1} \rangle$ .

# New way for fast multiplication of polynomials

- To multiply two polynomials  $P_A(x)$  and  $P_B(x)$  of degree (at most)  $n$  we will evaluate them at the roots of unity of order  $2n + 1$  (instead of at  $-n, \dots, -1, 0, 1, \dots, n$  as in Karatsuba's method!)
- This produces the DFT of the (0 padded) sequence of their coefficients  $(A_0, A_1, \dots, A_n, \underbrace{0, \dots, 0}_n)$ .
- We will then multiply the corresponding values  $P_A(\omega_{2n+1}^k)$  and  $P_B(\omega_{2n+1}^k)$ .
- We then use the inverse transformation for DFT, called IDFT, to recover the coefficients of the product polynomial from its values at these roots of unity.

# New way for fast multiplication of polynomials

$$P_A(x) = A_0 + \dots + A_n x^n + 0 \cdot x^{n+1} + \dots + 0 \cdot x^{2n}; P_B(x) = B_0 + \dots + B_n x^n + 0 \cdot x^{n+1} + \dots + 0 \cdot x^{2n}$$

↓ DFT

↓ DFT

$$\{P_A(1), P_A(\omega_{2n+1}), P_A(\omega_{2n+1}^2), \dots, P_A(\omega_{2n+1}^{2n})\}; \quad \{P_B(1), P_B(\omega_{2n+1}), P_B(\omega_{2n+1}^2), \dots, P_B(\omega_{2n+1}^{2n})\}$$

↓ multiplication

$$\{P_A(1)P_B(1), P_A(\omega_{2n+1})P_B(\omega_{2n+1}), \dots, P_A(\omega_{2n+1}^{2n})P_B(\omega_{2n+1}^{2n})\}$$

↓ IDFT

$$P_C(x) = \sum_{j=0}^{2n} \underbrace{\left( \sum_{i=0}^j A_i B_{j-i} \right)}_{C_j} x^j = \sum_{j=0}^{2n} C_j x^j = P_A(x) \cdot P_B(x)$$

# Fast multiplication of polynomials

- Multiplying  $2n + 1$  values of  $P_A(\omega_{2n+1}^k)$  and  $P_B(\omega_{2n+1}^k)$  is done in linear time.
- So we have to find an efficient way to compute DFT and IDFT.
- For each fixed  $k$  we need to evaluate

$$P_A(\omega_{2n+1}^k) = A_0 + A_1\omega_{2n+1}^k + A_2\omega_{2n+1}^{2k} + \dots + A_n\omega_{2n+1}^{nk}$$

$$P_B(\omega_{2n+1}^k) = B_0 + B_1\omega_{2n+1}^k + B_2\omega_{2n+1}^{2k} + \dots + B_n\omega_{2n+1}^{nk}$$

- We could precompute all of the values  $\omega_{2n+1}^k$ , but, by brute force, for each  $k$  we would have to do  $n + 1$  multiplications of the form  $A_m \cdot \omega_{2n+1}^{km}$ , for  $0 \leq m \leq n$ .
- Thus, since  $m$  ranges from 0 to  $n$ , we would have to do  $O(n^2)$  multiplications.
- Can we do it faster??
- This is precisely what the **Fast Fourier Transform (FFT)** does; it computes the values  $P_A(\omega_n^k)$  for all  $k$  such that  $0 \leq k < n$  in  $O(n \log n)$  time.

# The Fast Fourier Transform (FFT)

- Let  $P_A(x) = A_0 + A_1x + \dots + A_{n-1}x^{n-1}$ ;
  - We can assume that  $n$  is a power of 2 - otherwise we can pad  $P_A(x)$  with zero coefficients until its degree becomes equal to the nearest power of 2.
  - Exercise: Show that for every  $n$  which is not a power of two the smallest power of 2 larger or equal to  $n$  is smaller than  $2n$ .
  - *Hint*: consider  $n$  in binary. How many bits does the nearest power of two have?

# The Fast Fourier Transform (FFT)

- **The main idea of the FFT algorithm:** divide-and-conquer by splitting the polynomial into the even powers and the odd powers:

$$\begin{aligned}P_A(x) &= (A_0 + A_2x^2 + A_4x^4 + \dots + A_{n-2}x^{n-2}) + (A_1x + A_3x^3 + \dots + A_{n-1}x^{n-1}) \\&= A_0 + A_2x^2 + A_4(x^2)^2 + \dots + A_{n-2}(x^2)^{\frac{n}{2}-1} \\&\quad + x \left( A_1 + A_3x^2 + A_5(x^2)^2 + \dots + A_{n-1}(x^2)^{\frac{n}{2}-1} \right)\end{aligned}$$

- Let us define

$$A^0(y) = A_0 + A_2y + A_4y^2 + \dots + A_{n-2}y^{\frac{n}{2}-1}$$

$$A^1(y) = A_1 + A_3y + A_5y^2 + \dots + A_{n-1}y^{\frac{n}{2}-1}$$

- Then

$$P_A(x) = A^0(x^2) + x A^1(x^2)$$

- Note that the degree of the polynomials  $A^0(y)$  and  $A^1(y)$  is  $n/2 - 1$ , while the degree of the polynomial  $P_A(x)$  is  $n - 1$ . Thus, the degree of the polynomials  $A^0(y)$  and  $A^1(y)$  is only about one half of the degree of the polynomial  $P_A(x)$ .

# The Fast Fourier Transform (FFT)

- **Problem of size  $n$ :**

*Evaluate a polynomial of degree  $n - 1$  at  $n$  many roots of unity.*

- **Problem of size  $n/2$ :**

*Evaluate a polynomial of degree  $n/2 - 1$  at  $n/2$  many roots of unity.*

- We reduced evaluation of our polynomial  $P_A(x)$  of degree  $n - 1$  at inputs  $x = \omega_n^0, x = \omega_n^1, x = \omega_n^2, \dots, x = \omega_n^{n-1}$  to evaluation of two polynomials  $A^0(y)$  and  $A^1(y)$  of degree  $n/2 - 1$ , at points  $y = x^2$  for the same values of inputs  $x$ .
- However, as  $x$  ranges through values  $\{\omega_n^0, \omega_n^1, \omega_n^2, \dots, \omega_n^{n-1}\}$ , the value of  $y = x^2$  ranges through  $\{\omega_{n/2}^0, \omega_{n/2}^1, \omega_{n/2}^2, \dots, \omega_{n/2}^{n/2-1}\}$ , and there are only  $n/2$  distinct such values.
- Once we get these  $n/2$  values of  $A^0(x^2)$  and  $A^1(x^2)$  we need  $n$  additional multiplications with numbers  $\omega_n^k$  to obtain the values of

$$\begin{aligned} P_A(\omega_n^k) &= A^0((\omega_n^k)^2) + \omega_n^k \cdot A^1((\omega_n^k)^2) \\ &= A^0(\omega_{n/2}^k) + \omega_n^k \cdot A^1(\omega_{n/2}^k). \end{aligned}$$

- Thus, we have reduced a problem of size  $n$  to two such problems of size  $n/2$ , plus a linear overhead.

# The Fast Fourier Transform (FFT) - a simplification

- Note that by the Cancellation Lemma  $\omega_n^{\frac{n}{2}} = \omega_{2\frac{n}{2}}^{\frac{n}{2}} = \omega_2 = -1$ ; thus,

$$\omega_n^{k+\frac{n}{2}} = \omega_n^{\frac{n}{2}} \omega_n^k = \omega_2 \omega_n^k = -\omega_n^k;$$

- We can now simplify evaluation of

$$P_A(\omega_n^k) = A^0((\omega_n^k)^2) + \omega_n^k A^1((\omega_n^k)^2)$$

for  $k > n/2$  as follows: let  $k = \frac{n}{2} + m$ ; then

$$\begin{aligned} P_A(\omega_n^{\frac{n}{2}+m}) &= A^0((\omega_n^{\frac{n}{2}+m})^2) + \omega_n^{\frac{n}{2}+m} A^1((\omega_n^{\frac{n}{2}+m})^2) \\ &= A^0(\omega_n^{n+2m}) + \omega_n^{\frac{n}{2}} \omega_n^m A^1(\omega_n^{n+2m}) \\ &= A^0(\omega_n^n \omega_n^{2m}) + \omega_{2\frac{n}{2}}^{\frac{n}{2}} \omega_n^m A^1(\omega_n^n \omega_n^{2m}) \\ &= A^0(\omega_n^{2m}) + \omega_2 \omega_n^m A^1(\omega_n^{2m}) \\ &= A^0((\omega_n^m)^2) - \omega_n^m A^1((\omega_n^m)^2) \end{aligned}$$

- Compare this with  $P_A(\omega_n^m) = A^0((\omega_n^m)^2) + \omega_n^m A^1((\omega_n^m)^2)$

# The Fast Fourier Transform (FFT) - a simplification

- So we can replace evaluations of

$$\begin{aligned}P_A(\omega_n^k) &= A^0((\omega_n^k)^2) + \omega_n^k A^1((\omega_n^k)^2) \\ &= A^0(\omega_{n/2}^k) + \omega_n^k A^1(\omega_{n/2}^k)\end{aligned}$$

for  $k = 0$  to  $k = n - 1$

with such evaluations only for  $k = 0$  to  $k = n/2 - 1$

and just let for  $k = 0$  to  $k = n/2 - 1$

$$\begin{aligned}P_A(\omega_n^{\frac{n}{2}+k}) &= A^0((\omega_n^k)^2) - \omega_n^k A^1((\omega_n^k)^2) \\ &= A^0(\omega_{n/2}^k) - \omega_n^k A^1(\omega_{n/2}^k)\end{aligned}$$

- We can now write a pseudo-code for our FFT algorithm:

# FFT algorithm

```
1: function FFT( $A$ )
2:    $n \leftarrow \text{length}[A]$ 
3:   if  $n = 1$  then return  $A$ 
4:   else
5:      $A^{[0]} \leftarrow (A_0, A_2, \dots, A_{n-2})$ ;
6:      $A^{[1]} \leftarrow (A_1, A_3, \dots, A_{n-1})$ ;
7:      $y^{[0]} \leftarrow \text{FFT}(A^{[0]})$ ;
8:      $y^{[1]} \leftarrow \text{FFT}(A^{[1]})$ ;
9:      $\omega_n \leftarrow e^{i\frac{2\pi}{n}}$ ;
10:     $\omega \leftarrow 1$ ;
11:    for  $k = 0$  to  $k = \frac{n}{2} - 1$  do;
12:       $y_k \leftarrow y_k^{[0]} + \omega \cdot y_k^{[1]}$ ;
13:       $y_{\frac{n}{2}+k} \leftarrow y_k^{[0]} - \omega \cdot y_k^{[1]}$ 
14:       $\omega \leftarrow \omega \cdot \omega_n$ ;
15:    end for
16:    return  $y$ 
17:  end if
18: end function
```

# How fast is the Fast Fourier Transform?

- We have recursively reduced evaluation of a polynomial  $P_A(x)$  of degree  $n - 1$  at  $n$  roots of unity of order  $n$  to evaluations of two polynomials  $A^0(y)$  and  $A^1(y)$ , each of degree  $n/2 - 1$ , at  $n/2$  many roots of unity of order  $n/2$ .
- Once we get these  $n/2$  values of  $A^0(y)$  and  $A^1(y)$  we need  $n/2$  additional multiplications to obtain the values of

$$P_A(\omega_n^k) = A^0(\omega_{n/2}^k) + \omega_n^k A^1(\omega_{n/2}^k)$$

and

$$P_A(\omega_n^{\frac{n}{2}+k}) = A^0(\omega_{n/2}^k) - \omega_n^k A^1(\omega_{n/2}^k)$$

- Thus, we have reduced a problem of size  $n$  to two such problems of size  $n/2$ , plus a linear overhead.
- Consequently, our algorithm's run time satisfies the recurrence

$$T(n) = 2T\left(\frac{n}{2}\right) + cn$$

- The Master Theorem gives  $T(n) = \Theta(n \log n)$ .

# Matrix representation of polynomial evaluation

- Evaluation of a polynomial  $P_A(x) = A_0 + A_1x + \dots + A_{n-1}x^{n-1}$  at roots of unity  $\omega_n^k$  of order  $n$  can be represented in the matrix form as follows:

$$\begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n & \omega_n^2 & \dots & \omega_n^{n-1} \\ 1 & \omega_n^2 & \omega_n^{2 \cdot 2} & \dots & \omega_n^{2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \omega_n^{n-1} & \omega_n^{2(n-1)} & \dots & \omega_n^{(n-1)(n-1)} \end{pmatrix} \begin{pmatrix} A_0 \\ A_1 \\ A_2 \\ \vdots \\ A_{n-1} \end{pmatrix} = \begin{pmatrix} P_A(1) \\ P_A(\omega_n) \\ P_A(\omega_n^2) \\ \vdots \\ P_A(\omega_n^{n-1}) \end{pmatrix} \quad (3)$$

- The FFT is just a method of replacing this matrix-vector multiplication taking  $n^2$  many multiplications with an  $n \log n$  procedure.
- From  $P_A(1) = P_A(\omega_n^0)$ ,  $P_A(\omega_n)$ ,  $P_A(\omega_n^2), \dots, P_A(\omega_n^{n-1})$ , we get the coefficients from

$$\begin{pmatrix} A_0 \\ A_1 \\ A_2 \\ \vdots \\ A_{n-1} \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n & \omega_n^2 & \dots & \omega_n^{n-1} \\ 1 & \omega_n^2 & \omega_n^{2 \cdot 2} & \dots & \omega_n^{2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \omega_n^{n-1} & \omega_n^{2(n-1)} & \dots & \omega_n^{(n-1)(n-1)} \end{pmatrix}^{-1} \begin{pmatrix} P_A(1) \\ P_A(\omega_n) \\ P_A(\omega_n^2) \\ \vdots \\ P_A(\omega_n^{n-1}) \end{pmatrix} \quad (4)$$

# Recall our strategy for fast multiplication of polynomials

- Another remarkable feature of the roots of unity: to obtain the inverse of the above matrix, all we have to do is just change the signs of the exponents and divide everything by  $n$ :

$$\begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n & \omega_n^2 & \dots & \omega_n^{n-1} \\ 1 & \omega_n^2 & \omega_n^{2 \cdot 2} & \dots & \omega_n^{2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \omega_n^{n-1} & \omega_n^{2(n-1)} & \dots & \omega_n^{(n-1)(n-1)} \end{pmatrix}^{-1} = \frac{1}{n} \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n^{-1} & \omega_n^{-2} & \dots & \omega_n^{-(n-1)} \\ 1 & \omega_n^{-2} & \omega_n^{-2 \cdot 2} & \dots & \omega_n^{-2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \omega_n^{-(n-1)} & \omega_n^{-2(n-1)} & \dots & \omega_n^{-(n-1)(n-1)} \end{pmatrix}$$

To see this, note that if we compute the product

$$\begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n & \omega_n^2 & \dots & \omega_n^{n-1} \\ 1 & \omega_n^2 & \omega_n^{2 \cdot 2} & \dots & \omega_n^{2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \omega_n^{n-1} & \omega_n^{2(n-1)} & \dots & \omega_n^{(n-1)(n-1)} \end{pmatrix} \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n^{-1} & \omega_n^{-2} & \dots & \omega_n^{-(n-1)} \\ 1 & \omega_n^{-2} & \omega_n^{-2 \cdot 2} & \dots & \omega_n^{-2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \omega_n^{-(n-1)} & \omega_n^{-2(n-1)} & \dots & \omega_n^{-(n-1)(n-1)} \end{pmatrix}$$

the  $(i, j)$  entry in the product matrix is equal to a product of  $i^{th}$  row and  $j^{th}$  column:

$$\begin{pmatrix} 1 & \omega_n^i & \omega_n^{2 \cdot i} & \dots & \omega_n^{i \cdot (n-1)} \end{pmatrix} \begin{pmatrix} 1 \\ \omega_n^{-j} \\ \omega_n^{-2j} \\ \vdots \\ \omega_n^{-(n-1)j} \end{pmatrix} = \sum_{k=0}^{n-1} \omega_n^{ik} \omega_n^{-jk} = \sum_{k=0}^{n-1} \omega_n^{(i-j)k}$$

# Recall our strategy for fast multiplication of polynomials

We now have two possibilities:

①  $i = j$ : then

$$\sum_{k=0}^{n-1} \omega_n^{(i-j)k} = \sum_{k=0}^{n-1} \omega_n^0 = \sum_{k=0}^{n-1} 1 = n;$$

②  $i \neq j$ : then  $\sum_{k=0}^{n-1} \omega_n^{(i-j)k}$  represents a geometric series with the ratio  $\omega_n^{i-j}$  and thus

$$\sum_{k=0}^{n-1} \omega_n^{(i-j)k} = \frac{1 - \omega_n^{(i-j)n}}{1 - \omega_n^{i-j}} = \frac{1 - (\omega_n^n)^{i-j}}{1 - \omega_n^{i-j}} = \frac{1 - 1}{1 - \omega_n^{i-j}} = 0$$

So,

$$\begin{pmatrix} 1 & \omega_n^i & \omega_n^{2i} & \dots & \omega_n^{i(n-1)} \end{pmatrix} \begin{pmatrix} 1 \\ \omega_n^{-j} \\ \omega_n^{-2j} \\ \vdots \\ \omega_n^{-(n-1)j} \end{pmatrix} = \sum_{k=0}^{n-1} \omega_n^{(i-j)k} = \begin{cases} n & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases}$$

(5)

So we get:

$$\begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n & \omega_n^2 & \dots & \omega_n^{n-1} \\ 1 & \omega_n^2 & \omega_n^{2 \cdot 2} & \dots & \omega_n^{2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \omega_n^{n-1} & \omega_n^{2(n-1)} & \dots & \omega_n^{(n-1)(n-1)} \end{pmatrix} \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n^{-1} & \omega_n^{-2} & \dots & \omega_n^{-(n-1)} \\ 1 & \omega_n^{-2} & \omega_n^{-2 \cdot 2} & \dots & \omega_n^{-2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \omega_n^{-(n-1)} & \omega_n^{-2(n-1)} & \dots & \omega_n^{-(n-1)(n-1)} \end{pmatrix} \\
 = \begin{pmatrix} n & 0 & 0 & \dots & 0 \\ 0 & n & 0 & \dots & 0 \\ 0 & 0 & n & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & n \end{pmatrix}$$

i.e.,

$$\begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n & \omega_n^2 & \dots & \omega_n^{n-1} \\ 1 & \omega_n^2 & \omega_n^{2 \cdot 2} & \dots & \omega_n^{2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \omega_n^{n-1} & \omega_n^{2(n-1)} & \dots & \omega_n^{(n-1)(n-1)} \end{pmatrix}^{-1} = \frac{1}{n} \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n^{-1} & \omega_n^{-2} & \dots & \omega_n^{-(n-1)} \\ 1 & \omega_n^{-2} & \omega_n^{-2 \cdot 2} & \dots & \omega_n^{-2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & \omega_n^{-(n-1)} & \omega_n^{-2(n-1)} & \dots & \omega_n^{-(n-1)(n-1)} \end{pmatrix}$$

- We now have

$$\begin{aligned} \begin{pmatrix} A_0 \\ A_1 \\ A_2 \\ \vdots \\ A_{n-1} \end{pmatrix} &= \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n & \omega_n^2 & \dots & \omega_n^{n-1} \\ 1 & \omega_n^2 & \omega_n^{2 \cdot 2} & \dots & \omega_n^{2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \omega_n^{n-1} & \omega_n^{2(n-1)} & \dots & \omega_n^{(n-1)(n-1)} \end{pmatrix}^{-1} \begin{pmatrix} P_A(1) \\ P_A(\omega_n) \\ P_A(\omega_n^2) \\ \vdots \\ P_A(\omega_n^{n-1}) \end{pmatrix} = \\ &= \frac{1}{n} \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n^{-1} & \omega_n^{-2} & \dots & \omega_n^{-(n-1)} \\ 1 & \omega_n^{-2} & \omega_n^{-2 \cdot 2} & \dots & \omega_n^{-2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \omega_n^{-(n-1)} & \omega_n^{-2(n-1)} & \dots & \omega_n^{-(n-1)(n-1)} \end{pmatrix} \begin{pmatrix} P_A(1) \\ P_A(\omega_n) \\ P_A(\omega_n^2) \\ \vdots \\ P_A(\omega_n^{n-1}) \end{pmatrix} \end{aligned}$$

- This means that to convert from the values

$$\langle P_A(1), P_A(\omega_n), P_A(\omega_n^2), \dots, P_A(\omega_n^{n-1}) \rangle$$

back to the coefficient form

$$P_A(x) = A_0 + A_1x + A_2x^2 + \dots + A_{n-1}x^{n-1}$$

we can use **the same** FFT algorithm with the only change that:

- 1 the root of unity  $\omega_n$  is replaced by  $\overline{\omega_n} = \omega_n^{-1} = e^{-i\frac{2\pi}{n}}$ ,
- 2 the resulting output values are divided by  $n$ .

# Inverse Fast Fourier Transform (IFFT):

```
1: function IFFT*(A)
2:    $n \leftarrow \text{length}(A)$ 
3:   if  $n = 1$  then return  $A$ 
4:   else
5:      $A^{[0]} \leftarrow (A_0, A_2, \dots, A_{n-2})$ ;
6:      $A^{[1]} \leftarrow (A_1, A_3, \dots, A_{n-1})$ ;
7:      $y^{[0]} \leftarrow \text{IFFT}^*(A^{[0]})$ ;
8:      $y^{[1]} \leftarrow \text{IFFT}^*(A^{[1]})$ ;
9:      $\omega_n \leftarrow e^{-i\frac{2\pi}{n}}$ ; ⇐ different from FFT
10:     $\omega \leftarrow 1$ ;
11:    for  $k = 0$  to  $k = \frac{n}{2} - 1$  do;
12:       $y_k \leftarrow y_k^{[0]} + \omega \cdot y_k^{[1]}$ ;
13:       $y_{\frac{n}{2}+k} \leftarrow y_k^{[0]} - \omega \cdot y_k^{[1]}$ 
14:       $\omega \leftarrow \omega \cdot \omega_n$ ;
15:    end for
16:    return  $y$ ;
17:  end if
18: end function
```

```
1: function IFFT(A) ⇐ different from FFT
2:   return  $\text{IFFT}^*(A)/\text{length}(A)$ 
3: end function
```

# More on DFT

- We have followed the textbook (CLRS).
- However, what CLRS calls DFT, namely, the sequence

$$\langle P_A(\omega_n^0), P_A(\omega_n^1), P_A(\omega_n^2), \dots, P_A(\omega_n^{n-1}) \rangle$$

is usually considered the Inverse Discrete Fourier Transform (IDFT) of the sequence of the coefficients

$$\langle A_0, A_1, A_2, \dots, A_{n-1} \rangle$$

of the polynomial  $P_A(x)$ ;

- Instead,

$$\langle P_A(\omega_n^0), P_A(\omega_n^{-1}), P_A(\omega_n^{-2}), \dots, P_A(\omega_n^{-(n-1)}) \rangle$$

is considered the “forward operation” i.e., the DFT.

- Taking this as the “forward operation” has an important conceptual advantage and is used more often than the textbook’s choice, especially in electrical engineering literature.

# More on DFT

- Another “tweak” of DFT: note that

$$\begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n & \omega_n^2 & \dots & \omega_n^{n-1} \\ 1 & \omega_n^2 & \omega_n^{2 \cdot 2} & \dots & \omega_n^{2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \omega_n^{n-1} & \omega_n^{2(n-1)} & \dots & \omega_n^{(n-1)(n-1)} \end{pmatrix} \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & \omega_n^{-1} & \omega_n^{-2} & \dots & \omega_n^{-(n-1)} \\ 1 & \omega_n^{-2} & \omega_n^{-2 \cdot 2} & \dots & \omega_n^{-2 \cdot (n-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \omega_n^{-(n-1)} & \omega_n^{-2(n-1)} & \dots & \omega_n^{-(n-1)(n-1)} \end{pmatrix} \\ = n \begin{pmatrix} 1 & 0 & 0 & \dots & 0 \\ 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & 1 \end{pmatrix}$$

implies:

# More on DFT

$$\begin{pmatrix} \frac{1}{\sqrt{n}} & \frac{1}{\sqrt{n}} & \frac{1}{\sqrt{n}} & \vdots & \frac{1}{\sqrt{n}} \\ \frac{1}{\sqrt{n}} & \frac{\omega_n}{\sqrt{n}} & \frac{\omega_n^2}{\sqrt{n}} & \vdots & \frac{\omega_n^{n-1}}{\sqrt{n}} \\ \frac{1}{\sqrt{n}} & \frac{\omega_n^2}{\sqrt{n}} & \frac{\omega_n^{2 \cdot 2}}{\sqrt{n}} & \vdots & \frac{\omega_n^{2 \cdot (n-1)}}{\sqrt{n}} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \frac{1}{\sqrt{n}} & \frac{\omega_n^{n-1}}{\sqrt{n}} & \frac{\omega_n^{2(n-1)}}{\sqrt{n}} & \vdots & \frac{\omega_n^{(n-1)(n-1)}}{\sqrt{n}} \end{pmatrix} \begin{pmatrix} \frac{1}{\sqrt{n}} & \frac{1}{\sqrt{n}} & \frac{1}{\sqrt{n}} & \vdots & \frac{1}{\sqrt{n}} \\ \frac{1}{\sqrt{n}} & \frac{\omega_n^{-1}}{\sqrt{n}} & \frac{\omega_n^{-2}}{\sqrt{n}} & \vdots & \frac{\omega_n^{-(n-1)}}{\sqrt{n}} \\ \frac{1}{\sqrt{n}} & \frac{\omega_n^{-2}}{\sqrt{n}} & \frac{\omega_n^{-2 \cdot 2}}{\sqrt{n}} & \vdots & \frac{\omega_n^{-2 \cdot (n-1)}}{\sqrt{n}} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \frac{1}{\sqrt{n}} & \frac{\omega_n^{-(n-1)}}{\sqrt{n}} & \frac{\omega_n^{-2(n-1)}}{\sqrt{n}} & \vdots & \frac{\omega_n^{-(n-1)(n-1)}}{\sqrt{n}} \end{pmatrix} \\
 = \begin{pmatrix} 1 & 0 & 0 & \dots & 0 \\ 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 \end{pmatrix}$$

Thus, these two matrices are inverses of each other.

# More on DFT

- This motivates us to “tweak” the definition of DFT:
- Given a sequence of numbers  $\vec{A} = (A_0, A_1, \dots, A_{n-1})$  the Discrete Fourier Transform of this sequence is the sequence of the values of the polynomial

$$P_A^*(x) = \frac{1}{\sqrt{n}} P_A(x) = \frac{1}{\sqrt{n}} (A_0 + A_1 x + \dots + A_{n-1} x^{n-1})$$

for  $x = \omega_n^{-k}$  for  $k = 0, \dots, n-1$ ; i.e., the sequence of values  $P_A^*(\omega_n^{-k})$ :

$$P_A^*(\omega_n^{-k}) = \frac{1}{\sqrt{n}} (A_0 + A_1 (\omega_n^{-k})^1 + \dots + A_{n-1} (\omega_n^{-k})^{n-1})$$

- Given a sequence of numbers  $(A_0, A_1, \dots, A_{n-1})$  the **Inverse Discrete Fourier Transform** of this sequence is the sequence of the values of the same polynomial

$$P_A^*(x) = \frac{1}{\sqrt{n}} (A_0 + A_1 x + \dots + A_{n-1} x^{n-1})$$

but for  $x = \omega_n^k$  for  $k = 0, \dots, n-1$ ; i.e., the sequence of values  $P_A^*(\omega_n^k)$

$$P_A^*(\omega_n^k) = \frac{1}{\sqrt{n}} (A_0 + A_1 (\omega_n^k)^1 + \dots + A_{n-1} (\omega_n^k)^{n-1})$$

# More on DFT

```
1: function FFT*(A)
2:    $n \leftarrow \text{length}[A]$ 
3:   if  $n = 1$  then return A
4:   else
5:      $A^{[0]} \leftarrow (A_0, A_2, \dots, A_{n-2})$ ;
6:      $A^{[1]} \leftarrow (A_1, A_3, \dots, A_{n-1})$ ;
7:      $y^{[0]} \leftarrow FFT^*(A^{[0]})$ ;
8:      $y^{[1]} \leftarrow FFT^*(A^{[1]})$ ;
9:      $\omega_n \leftarrow e^{-i\frac{2\pi}{n}}$ ;
10:     $\omega \leftarrow 1$ ;
11:    for  $k = 0$  to  $k = \frac{n}{2} - 1$  do;
12:       $y_k \leftarrow y_k^{[0]} + \omega \cdot y_k^{[1]}$ ;
13:       $y_{\frac{n}{2}+k} \leftarrow y_k^{[0]} - \omega \cdot y_k^{[1]}$ 
14:       $\omega \leftarrow \omega \cdot \omega_n$ ;
15:    end for
16:    return y;
17:  end if
18: end function
```

```
1: function FFT(A)
2:   return  $FFT^*(A)/\sqrt{\text{length}(A)}$ ;
3: end function
```

```
1: function IFFT*(A)
2:    $n \leftarrow \text{length}[A]$ 
3:   if  $n = 1$  then return A
4:   else
5:      $A^{[0]} \leftarrow (A_0, A_2, \dots, A_{n-2})$ ;
6:      $A^{[1]} \leftarrow (A_1, A_3, \dots, A_{n-1})$ ;
7:      $y^{[0]} \leftarrow IFFT^*(A^{[0]})$ ;
8:      $y^{[1]} \leftarrow IFFT^*(A^{[1]})$ ;
9:      $\omega_n \leftarrow e^{i\frac{2\pi}{n}}$ ;
10:     $\omega \leftarrow 1$ ;
11:    for  $k = 0$  to  $k = \frac{n}{2} - 1$  do;
12:       $y_k \leftarrow y_k^{[0]} + \omega \cdot y_k^{[1]}$ ;
13:       $y_{\frac{n}{2}+k} \leftarrow y_k^{[0]} - \omega \cdot y_k^{[1]}$ 
14:       $\omega \leftarrow \omega \cdot \omega_n$ ;
15:    end for
16:    return y;
17:  end if
18: end function
```

```
1: function IFFT(A)
2:   return  $IFFT^*(A)/\sqrt{\text{length}(A)}$ ;
3: end function
```

# Back to fast multiplication of polynomials (convolution)

$$P_A(x) = A_0 + A_1x + \dots + A_nx^n$$

$$P_B(x) = B_0 + B_1x + \dots + B_nx^n$$

$$\Downarrow \text{ DFT } \quad O(n \log n)$$

$$\Downarrow \text{ DFT } \quad O(n \log n)$$

$$\{P_A(1), P_A(\omega_{2n+1}), P_A(\omega_{2n+1}^2), \dots, P_A(\omega_{2n+1}^{2n})\}; \quad \{P_B(1), P_B(\omega_{2n+1}), P_B(\omega_{2n+1}^2), \dots, P_B(\omega_{2n+1}^{2n})\}$$

$$\Downarrow \text{ multiplication } \quad O(n)$$

$$\{P_A(1)P_B(1), P_A(\omega_{2n+1})P_B(\omega_{2n+1}), \dots, P_A(\omega_{2n+1}^{2n})P_B(\omega_{2n+1}^{2n})\}$$

$$\Downarrow \text{ IDFT } \quad O(n \log n)$$

$$P_C(x) = \sum_{j=0}^{2n} \underbrace{\left( \sum_{i=0}^j A_i B_{j-i} \right)}_{C_j} x^j = \sum_{j=0}^{2n} C_j x^j = P_A(x) \cdot P_B(x)$$

Thus, convolution can be computed in time  $O(n \log n)$ .

# Interpretation of DFT

- The **scalar product** (also called *dot product*) of two vectors with real coordinates,  $\vec{x} = (x_0, x_1, \dots, x_{n-1})$  and  $\vec{y} = (y_0, y_1, \dots, y_{n-1})$ , denoted by  $\langle \vec{x}, \vec{y} \rangle$  is defined as

$$\langle \vec{x}, \vec{y} \rangle = \sum_{i=0}^{n-1} x_i y_i$$

- If the coordinates of our vectors are complex numbers, then the scalar product of such two vectors is defined as

$$\langle \vec{x}, \vec{y} \rangle = \sum_{i=0}^{n-1} x_i \overline{y_i}$$

- Recall that  $\bar{z}$  denotes the complex conjugate of  $z$ , i.e.,  $\overline{a + ib} = a - ib$ .
- The **norm** of a vector  $\vec{x} = (x_0, x_1, \dots, x_{n-1})$  is defined as

$$\|\vec{x}\| = \sqrt{\langle \vec{x}, \vec{x} \rangle} = \sqrt{\sum_{i=0}^{n-1} x_i \overline{x_i}} = \sqrt{\sum_{i=0}^{n-1} |x_i|^2}$$

# Interpretation of DFT

- Note that

$$\begin{aligned}\overline{\omega_n^k} &= \overline{e^{i \frac{2\pi k}{n}}} = \overline{\cos \frac{2\pi k}{n} + i \sin \frac{2\pi k}{n}} = \cos \frac{2\pi k}{n} - i \sin \frac{2\pi k}{n} \\ &= \cos \frac{-2\pi k}{n} + i \sin \frac{-2\pi k}{n} = e^{-i \frac{2\pi k}{n}} = \omega_n^{-k}\end{aligned}$$

- Thus, what we had before,

$$\left(1 \quad \omega_n^k \quad \omega_n^{2 \cdot k} \quad \dots \quad \omega_n^{k \cdot (n-1)}\right) \begin{pmatrix} 1 \\ \omega_n^{-m} \\ \omega_n^{-2m} \\ \vdots \\ \omega_n^{-(n-1)m} \end{pmatrix} = \sum_{j=0}^{n-1} \omega_n^{(k-m)j} = \begin{cases} n & \text{if } k = m \\ 0 & \text{if } k \neq m \end{cases} \quad (6)$$

simply means that for  $k \neq m$  vectors  $\left(1, \omega_n^k, \omega_n^{2 \cdot k}, \dots, \omega_n^{k \cdot (n-1)}\right)$  and  $\left(1, \omega_n^m, \omega_n^{2 \cdot m}, \dots, \omega_n^{m \cdot (n-1)}\right)$  are mutually orthogonal and that their norm is equal to  $\sqrt{n}$ .

# Interpretation of DFT

- If we define 
$$\vec{e}_k = \frac{1}{\sqrt{n}} \left( 1, \omega_n^{k \cdot 1}, \omega_n^{k \cdot 2}, \dots, \omega_n^{k \cdot (n-1)} \right)$$
then  
and 
$$\|\vec{e}_k\| = \sqrt{\langle \vec{e}_k, \vec{e}_k \rangle} = 1$$
$$\langle \vec{e}_k, \vec{e}_m \rangle = 0 \quad \text{for } k \neq m$$
- Thus, the set of vectors  $\{\vec{e}_0, \vec{e}_1, \dots, \vec{e}_{n-1}\}$  is an orthonormal basis of the vector space of all complex valued sequences of length  $n$ .
- Let  $\vec{A} = (A_0, A_1, A_2, \dots, A_{n-1})$ ; then for

$$P_A^*(x) = \frac{1}{\sqrt{n}} (A_0 + A_1 x + \dots + A_{n-1} x^{n-1})$$

and the DFT of this sequence we have

$$\begin{aligned} P_A^*(\omega_n^{-k}) &= \frac{1}{\sqrt{n}} P_A(\omega_n^{-k}) = \frac{A_0}{\sqrt{n}} (\omega_n^{-k})^0 + \frac{A_1}{\sqrt{n}} (\omega_n^{-k})^1 + \frac{A_2}{\sqrt{n}} (\omega_n^{-k})^2 + \dots + \frac{A_{n-1}}{\sqrt{n}} (\omega_n^{-k})^{n-1} \\ &= A_0 \frac{(\overline{\omega_n^k})^0}{\sqrt{n}} + A_1 \frac{(\overline{\omega_n^k})^1}{\sqrt{n}} + A_2 \frac{(\overline{\omega_n^k})^2}{\sqrt{n}} + \dots + A_{n-1} \frac{(\overline{\omega_n^k})^{n-1}}{\sqrt{n}} \\ &= \left\langle (A_0, A_1, A_2, \dots, A_{n-1}), \left( \frac{(\omega_n^k)^0}{\sqrt{n}}, \frac{(\omega_n^k)^1}{\sqrt{n}}, \frac{(\omega_n^k)^2}{\sqrt{n}}, \dots, \frac{(\omega_n^k)^{n-1}}{\sqrt{n}} \right) \right\rangle \\ &= \langle \vec{A}, \vec{e}_k \rangle \end{aligned}$$

- Thus, the DFT of a vector  $\vec{A}$  is simply the sequence of projections of  $\vec{A}$  onto the basis vectors  $\vec{e}_k$ , ( $k = 0, \dots, n-1$ ).

# Interpretation of DFT

- In an  $n$ -dimensional vector space  $V$  with an orthonormal basis  $\mathbf{B}$  every vector  $\vec{A}$  can be represented as a linear combination of the basis vectors with coefficients equal to the projections of  $\vec{A}$  onto the basis vectors, i.e., the scalar product  $\langle \vec{A}, \vec{e}_k \rangle$ :

$$\vec{A} = \langle \vec{A}, \vec{e}_0 \rangle \vec{e}_0 + \langle \vec{A}, \vec{e}_1 \rangle \vec{e}_1 + \dots + \langle \vec{A}, \vec{e}_{n-1} \rangle \vec{e}_{n-1}$$

Representing vector  $c$  as a linear combination of the basis vectors  $e_1, e_2, e_3$  with projections as coefficients

# Interpretation of DFT

- Thus, in our case

$$\begin{aligned}\vec{A} &= \langle \vec{A}, \vec{e}_0 \rangle \vec{e}_0 + \langle \vec{A}, \vec{e}_1 \rangle \vec{e}_1 + \dots + \langle \vec{A}, \vec{e}_{n-1} \rangle \vec{e}_{n-1} \\ &= P_A^*(\omega_n^0) \vec{e}_0 + P_A^*(\omega_n^{-1}) \vec{e}_1 + \dots + P_A^*(\omega_n^{-(n-1)}) \vec{e}_{n-1}\end{aligned}$$

- Looking at the  $k^{th}$  coordinate of both the left and the right side we get

$$\begin{aligned}A_k &= P_A^*(\omega_n^0) \frac{(\omega_n^0)^k}{\sqrt{n}} + P_A^*(\omega_n^{-1}) \frac{(\omega_n^{-1})^k}{\sqrt{n}} + \dots + P_A^*(\omega_n^{-(n-1)}) \frac{(\omega_n^{-(n-1)})^k}{\sqrt{n}} \\ &= \frac{1}{\sqrt{n}} \left( P_A^*(\omega_n^0) + P_A^*(\omega_n^{-1}) (\omega_n^{-1})^k + \dots + P_A^*(\omega_n^{-(n-1)}) (\omega_n^{-(n-1)})^k \right)\end{aligned}$$

- Thus,  $A_k$  is obtained by evaluating the polynomial

$$Q(x) = \frac{1}{\sqrt{n}} \left( P_A^*(1) + P_A^*(\omega_n^{-1})x + \dots + P_A^*(\omega_n^{-(n-1)})x^{n-1} \right)$$

at  $x = \omega_n^k$ .

- But this is precisely the Inverse Discrete Fourier Transform of the sequence

$$\left( P_A^*(1), P_A^*(\omega_n^{-1}), \dots, P_A^*(\omega_n^{-(n-1)}) \right)$$

# Interpretation of DFT

- Let us denote the usual orthonormal basis of  $\mathbb{C}^n$  by  $\mathcal{B}$ :

$$\vec{b}_0 = (1, 0, 0, 0, \dots, 0), \vec{b}_1 = (0, 1, 0, 0, \dots, 0), \dots, \vec{b}_{n-1} = (0, 0, 0, 0, \dots, 1)$$

and by  $\mathcal{F}$  the basis  $\mathcal{F} = \{\vec{e}_0, \vec{e}_1, \dots, \vec{e}_{n-1}\}$  where  $\vec{e}_k = \left( \frac{1}{\sqrt{n}}, \frac{\omega_n^{1 \cdot k}}{\sqrt{n}}, \frac{\omega_n^{2 \cdot k}}{\sqrt{n}}, \dots, \frac{\omega_n^{(n-1) \cdot k}}{\sqrt{n}} \right)$ .

- then

$$\vec{A} = (A_0, A_1, A_2, \dots, A_{n-1})_{\mathcal{B}} = A_0 \vec{b}_0 + A_1 \vec{b}_1 + A_2 \vec{b}_2 + \dots + A_{n-1} \vec{b}_{n-1}$$

and also

$$\vec{A} = (P_A(\omega_n^0), P_A(\omega_n^1), A_2, \dots, P_A(\omega_n^{n-1}))_{\mathcal{F}} = P_A^*(\omega_n^0) \vec{e}_0 + P_A^*(\omega_n^{-1}) \vec{e}_1 + \dots + P_A^*(\omega_n^{-(n-1)}) \vec{e}_{n-1}$$

- Thus, DFT is just a change of basis operation: it transforms the sequence of coordinates

$$(A_0, A_1, A_2, \dots, A_{n-1})_{\mathcal{B}}$$

of a vector  $\vec{A}$  in the basis  $\mathcal{B}$  into the sequence

$$\left( P_A^*(\omega_n^0), P_A(\omega_n^{-1}), \dots, P_A(\omega_n^{-(n-1)}) \right)_{\mathcal{F}}$$

of the coordinates of the same vector in the basis  $\mathcal{F}$ .

# Interpretation of DFT

- Basis  $\mathcal{F}$  is very important!
- Let us look again at the equation

$$\begin{aligned} A_k &= \frac{1}{\sqrt{n}} \left( P_A^*(\omega_n^0) + P_A^*(\omega_n^{-1})(\omega_n^1)^k + P_A^*(\omega_n^{-2})(\omega_n^2)^k + \dots + P_A^*(\omega_n^{-(n-1)})(\omega_n^{n-1})^k \right) \\ &= \frac{1}{\sqrt{n}} \left( P_A^*(\omega_n^0) + P_A^*(\omega_n^{-1})e^{i\frac{2\pi k}{n}} + P_A^*(\omega_n^{-2})e^{i\frac{2\pi 2k}{n}} + \dots + P_A^*(\omega_n^{-(n-1)})e^{i\frac{2\pi k(n-1)}{n}} \right) \end{aligned}$$

- Assume that  $A_k = A(k)$  is actually a sample of a signal  $A(t)$  at a time instant  $k$ ;
- Let us also consider  $e^{i\frac{2\pi mk}{n}}$  to be a sample of the function  $f_m(t) = e^{i\frac{2\pi m}{n}t}$  also at an instant  $k$ ;
- Note that  $f_m(t) = e^{i\frac{2\pi m}{n}t} = \cos\left(\frac{2\pi m}{n}t\right) + i\sin\left(\frac{2\pi m}{n}t\right)$ ;
- This means that the samples  $A(k)$  of the signal  $A(t)$  at instants  $t = 0, 1, \dots, n-1$  are represented as a linear combination of samples at these instants of sinusoids (also called pure harmonic oscillations)  $\cos\left(\frac{2\pi m}{n}t\right)$  and  $\sin\left(\frac{2\pi m}{n}t\right)$  of increasing frequencies  $\frac{2\pi \cdot 1}{n}, \frac{2\pi \cdot 2}{n}, \dots, \frac{2\pi \cdot (n-1)}{n}$ ;

# Interpretation of DFT

- Thus, in a sense the absolute value  $|P_A^*(\omega_n^{-m})|$  of the  $m^{th}$  coordinate  $P_A^*(\omega_n^{-m})$  in the basis  $\mathcal{F}$  tells us how much of the sinusoids  $\cos(\frac{2\pi m}{n}t)$  and  $\sin(\frac{2\pi m}{n}t)$  are present in the signal  $A(t)$ .
- This is very important in very many fields, ranging from astronomy (detecting planets orbiting distant stars), electrical engineering (signal and image processing), to economics (looking for cycles in economic indicators).
- We call this *spectral analysis*.
